Current overview of the Nexus prototype, posture, and architecture.

Public draft

Current overview of the Nexus prototype, posture, and architecture.

Nexus is the portable coordination substrate beneath Open World Assembly. It is still an early proof of concept, not a finished public platform.

Current Status

Nexus is live enough to demonstrate the core direction, but unstable enough that visitors should treat it as a demo.

- Some features are disabled, provisional, or represented by placeholders.
- Data models, routes, interface details, and workflows may change during development.
- The public demo is meant to show direction, not to serve as durable civic infrastructure yet.

What Nexus Is

Nexus is a packet-based coordination system for people, assemblies, initiatives, policies, discussions, trust signals, and future governance workflows.

It is designed so communities can coordinate without depending on a single platform as the source of truth.

What Nexus Is Not

Nexus is not a party, command structure, social network clone, or centralized authority.

It is infrastructure: a portable way to describe coordination, relationships, claims, decisions, and shared records.

Core Pattern

Nexus treats coordination as signed, inspectable records.

- Packets carry structured information.

- Signatures establish authorship and integrity.
- Relationships and attestations create trust context.
- Policies can define how a scope interprets participation and legitimacy.

Open World Assembly

OWA is the first public-facing implementation built on top of Nexus.

The public site explains the vision. Nexus demonstrates the machinery beneath it.

Development Direction

The near-term goal is stability before scale.

Priorities include clearer packet contracts, readable docs, safer write flows, better import/export tools, stronger trust and policy systems, and a more coherent public surface.
